REMARK ON MIXED FOLIATE GENERIC SUBMANIFOLDS

Barbara Opozda

This paper is in final form and no version of it will be submitted for publication elsewhere.

O. Let M'be a Kählerian manifold with a complex structure J' and a Hermitian metric (,). Let M be a real submanifold in M'. (,) will mean also the induced metric tensor field on M. The norm defined by (,) will be denoted by $\|\cdot\|$. We set

/- the normal bundle of TM in TM'

p - the projection onto TM in TM = TM $\oplus \mathcal{A}$,

n - the projection onto of in TM' = TM \oplus of,

P=poJ , y=ncJ',

 $\mathcal{H} = \mathbf{T} \mathbf{M} + \mathbf{J}' \mathbf{T} \mathbf{M} \quad \text{for } \mathbf{x} \in \mathbf{M} ,$

 \mathfrak{D}^{\perp} - the orthogonal complement to \mathfrak{D} in T.M.,

 \mathfrak{D}_{\circ} - the orthogonal complement to T M in \mathcal{X} ,

 \mathcal{JH} - the orthogonal complement to \mathcal{H} in TM^{\dagger} ,

∇', ∇ - the Riemannian connections on M and M respectively,
 D - the normal connection, i.e. the connection in √ induced by ∇',
 x , A - the second fundamental form and the second fundamental tensor respectively for M in M'.

R',R - the curvature tensors (of type (1.3) as well as of type (0,4)) associated with ∇ and ∇ respectively,

 $h(X,Y) = n J'\alpha(X,Y) - \alpha(X,PY).$

Since M' is Kählerian h $(X,Y) = (\nabla_X \psi)Y = \psi \nabla Y - D_{\chi \psi}Y$. Recall the equations of Gauss and Codazzi:

(0.1)
$$R^{i}(W,Z,X,Y) = R(W,Z,X,Y) + (\alpha(X,Z), \alpha(Y,W))$$

$$(0.2) \quad (R^{1}(X,Y)Z)^{\perp} = (\overline{\nabla}_{X})(Y,Z) - (\overline{\nabla}_{X})(X,Z)$$

for X, Y, Z, W \in T_xM, x \in M, where $^{\perp}$ denotes the normal part of a vector tangent to M $^{\prime}$.

If p and p' are J' - invariant planes in T_XM' , then the holomorphic bisectional curvature by p and p' is given by H' (p,p') = R'(X,Y,X,Y) + R'(J'X,Y,J'X,Y),

where X and Y are unit vectors in p and p 'respectively. If X,Y are arbitrary vectors tangent to M' at a point x , then we shall denote R'(X,Y,X,Y) + R'(J'X,Y,J'X,Y) by $H_D^{'}(X,Y)$.

A real submanifold of M is called generic if dim \mathfrak{D} is

constant on M. If M is generic, then we set $\mathfrak{D} = \bigcup_{\mathbf{x} \in M} \mathfrak{D}_{\mathbf{x}}$

$$\mathfrak{D}^{\perp} = \bigcup \mathfrak{D}^{\perp}, \quad \mathfrak{R} = \bigcup \mathfrak{R}, \quad \mathfrak{R} = \bigcup \mathfrak{R}_{\mathbf{x}}, \quad \mathfrak{D} = \bigcup \mathfrak{D}_{\mathbf{x}}.$$

 \mathfrak{D} , \mathfrak{D}^{\perp} , \mathfrak{N} , \mathfrak{I}^{\parallel} , \mathfrak{D} are vector bundles over M. The distribution \mathfrak{D} is called the holomorphic distribution. A real submanifold M of M' is called a CR - submanifold if $\mathfrak{J}^{'}\mathfrak{D}^{\perp}\subset\mathfrak{D}_{0}$. A CR - submanifold is a generic submanifold, [4]. A generic submanifold is called purely real (resp. holomorphic) if $\mathfrak{D}=\{0\}$ (resp. $\mathfrak{D}=\{0\}$) A generic submanifold is said to be proper if it is neither purely real nor holomorphic. A purely real CR - submanifold is called totally real. If M is a generic submanifold of M, then the induced \mathfrak{f} - structure on M is defined by

$$f(X) = \begin{cases} 0 & \text{for } X \in \mathfrak{D}^{\perp} \\ J^{1}X & \text{for } X \in \mathfrak{D} \end{cases}$$

By a generic product we mean a generic submanifold for which the almost product structure $(\mathfrak{D},\mathfrak{D}^1)$ is parallel. Of course, it is equivalent to the fact, that M is locally the Riemannian product of a holomorphic submanifold of M and a purely real submanifold of M is Since M is Kählerian the parallelity of f is equivalent

to the parallelity of $(\mathfrak{D}, \mathfrak{D}^{\perp})$. In the next we shall use Proposition 0.1,[4]. ∇ f = 0 if and only if $\propto (X,Y) \in \mathcal{J} \mathcal{X}$ provided X or Y belongs to \mathfrak{D} .

A generic submanifold is said to be mixed totally geodesic if $\alpha(X,Y)=0$ for $X\in \mathfrak{D}$ and $Y\in \mathfrak{D}^{\perp}$, [2]. By a generic mixed foliate submanifold we shall mean a generic submanifold which is mixed totally geodesic and the holomorphic distribution $\mathfrak D$ is integrable.

This definition is analogous to the definition of a mixed foliate submanifold in the case of a CR - submanifold, [2]. A CR submanifold is mixed foliate if and only if the tensor field h is symmetric, [5].

1. B-Y Chen and S. Montiel proved in [3] the following theorems which generalize some earlier theorems.

Theorem 1.1. A generic submanifold in \mathbb{C}^n is a generic product if and only if it is mixed foliate

Theorem 1.2. Let M be a generic submanifold of a complexspace-form with positive holomorphic sectional curvature. If M is mixed foliate, then M is holomorphic or purely real.

we shall prove

Theorem 1.3. Let M be a generic mixed foliate submanifold of a Kählerian manifold M'. If the holomorphic bisectional curvature of M is non-negative, then M is a generic product. If M passes through a point of M' in which M' has positive holomorphic bisectional curvature, then M is holomorphic or purely real.

Proof. Suppose that M is a proper generic submanifold. Let $X \in \mathfrak{D}_{x}$ and $Y \in \mathfrak{D}_{x}^{\perp}$. Using the fact that $J'Y = PY + \gamma Y$ we find

(1.1)
$$2 R'(J'X,Y,X, \psi Y) = R'(X,PY,X,PY) - R'(X,\psi Y,X,\psi Y) - R'(X,J'Y,X,J'Y).$$

On the other hand

$$2 R^{1}(J^{1}X,Y,X,\psi Y) = -2 R^{1}(Y,X,J^{1}X,\psi Y) -2 R^{1}(X,J^{1}X,Y,\psi Y)$$

$$= -2 R^{1}(J^{12}X,Y,J^{1}X,\psi Y) -2 R^{1}(X,J^{1}X,Y,\psi Y).$$

Using the formula (1.1) for $R'(J'(J'X),Y,J'X,\psi'Y)$, we obtain. (1.2) $2R'(J'X,Y,X,\psi Y) = -R'(J'X,PY,J'X,PY)$

+
$$R^{1}(J^{1}X, \psi Y, J^{1}X, \psi Y) + R^{1}(X, Y, X, Y) =$$

- 2 $R^{1}(X, J^{1}X, Y, \psi Y)$

Since M is mixed totally geodesic A \mathfrak{P} \mathfrak{D} \mathfrak{D} . If follows that A X = A \mathfrak{T} X, where A \mathfrak{T} denotes the second fundamental tensor \mathfrak{P} \mathfrak{P} \mathfrak{P}

for a leaf of \mathfrak{D} in \mathbb{N}^{1} . By virtue of this fact, the facts that \mathbb{N} is mixed totally geodesic and \mathfrak{D} is involutive and by the equation of Codazzi, we have (comp.(6.6) and (6.7) in [3]) $(1.3) - R'(X,J'X,Y,\psi Y) = (R'(X,J'X)Y,\psi Y)$ $= (\alpha(X,\nabla_{J'X} Y),\psi Y) - (\alpha(J'X,\nabla_{Y} Y),\psi Y)$ $+ (\alpha(\nabla_{J'X} X - \nabla_{X} J'X,Y),\psi Y)$ $= (A X,\nabla_{J'X} Y) - (A J'X,\nabla_{Y} Y)$ $= (A X,\nabla_{J'X} Y) - (A J'X,\nabla_{Y} Y)$ $= (A X,\nabla_{J'X} Y) - (A J'X,\nabla_{J'} Y)$ $= (A X,\nabla_{J'X} Y) - (A J'X,\nabla_{J'} Y)$ $= (A^{T} X,A^{T} J'X) + (A^{T} J^{T}X,A^{T}X)$ $= (A^{T} X,A^{T} J'X) + (A^{T} J^{T}X,A^{T}X)$ $= (A^{T} X,A^{T} X)$ $= (A^{T} X,A^{T}$

= 2 $\|\mathbf{A}^{\mathsf{T}}_{\mathsf{J}} \mathbf{X}\|^2 + \|\mathbf{A}^{\mathsf{T}}_{\mathsf{J}} \mathbf{X}\|^2 - \|\mathbf{A}^{\mathsf{T}}_{\mathsf{PY}} \mathbf{X}\|^2 - \|\mathbf{A}^{\mathsf{T}}_{\mathsf{PY}} \mathbf{X}\|^2$

 $= \|A^{T}_{J} X\|^{2} + \|A^{T}_{J} X\|^{2} - \|A^{T}_{PY} X\|^{2} = \|A^{T}_{Q} X\|^{2} + \|A^{T}_{Y} X\|^{2}$

- ||AT x ||2

Combining this with (1.1) and (1.2), we obtain (1.4)
$$2 \|A^{\top} X\|^2 + 2 \|A^{\top} X\|^2 - 2 \|A^{\top} X\|^2$$

$$= H^{1} (X,PY) - H^{1} (X, \psi Y) - H^{1} (X,Y).$$

If we use this formula for PY instead of Y, we get (1.5) $2 \| \mathbf{A}^{\top} \| \mathbf{X} \|^2 + 2 \| \mathbf{A}^{\top} \| \mathbf{X} \|^2 - 2 \| \mathbf{A}^{\top} \| \mathbf{X} \|^2$ $= \mathbf{H}^{1} (\mathbf{X}, \mathbf{P}^2 \mathbf{Y}) - \mathbf{H}^{1} (\mathbf{X}, \mathbf{P}^2 \mathbf{Y}) - \mathbf{H}^{1} (\mathbf{X}, \mathbf{P}^2 \mathbf{Y})$

By virtue of (1.4) and (1.5) we have

(1.6)
$$2 \| \mathbf{A}^{\mathsf{T}} \mathbf{X} \|^2 + 2 \| \mathbf{A}^{\mathsf{T}} \mathbf{X} \|^2 + 2 \| \mathbf{A}^{\mathsf{T}} \mathbf{X} \|^2 - 2 \| \mathbf{A}^{\mathsf{T}} \mathbf{X} \|^2$$

$$= \mathbf{H}^1 (\mathbf{X}, \mathbf{P}^2 \mathbf{Y}) - \mathbf{H}^1 (\mathbf{X}, \mathbf{Y}) - \mathbf{H}^1 (\mathbf{X}, \mathbf{Y}) - \mathbf{H}^1 (\mathbf{X}, \mathbf{Y}) + \mathbf{H}^1 (\mathbf{X}, \mathbf{Y}) - \mathbf{H}^1 (\mathbf{X}, \mathbf{Y})$$

The tensor field P is skew-symmetric. In fact, $(Z,PW) = (Z,J^{\dagger}W) = -(J^{\dagger}Z,W) = -(PZ,W)$. Therefore P² is symmetric. Of Course

 $P^2(\mathfrak{D}^{\perp})\subset\mathfrak{D}^{\perp}$. Let Y Y be an ortonormal basis of \mathfrak{D}^{\perp} x

consisting of eigenvectors of $P^2|_{\mathfrak{D}_{\mathbf{X}}^{\perp}}$. Let $P^2(Y_i) = \lambda$; Y; for

i=1,...,k. Since $\|P^2Y_i\| \le \|Y_i\|$, $\lambda_1^2 \le 1$ for every i=1,...,k. The formula (1.6) used for $Y = Y_i$ has the form.

(1.7) $2 \|A^T X\|^2 + 2 \|A^T X\|^2 + (1 - \lambda_i^2) 2 \|A^T X\|^2 = Y_i$

= -
$$(1 - \lambda_1^2)$$
 $H_B^1(X, Y_i) - H_B^1(X, \psi Y_i) - H_B^1(X, \psi PY_i)$.

The left hand side of this equality is non-negative. If there is $x \in M$, $X \in \mathcal{D}_x$ and $i \in \{1, \dots, k\}$ such that the right hand side is negative, then we have a contradiction so M must be purely real or holomorphic. It holds, for instance, in the case where M passes through a point of M' in which the holomorphic bisectional curvature is positive. Now, suppose that the holomorphic bisectional curvature of M' is non-negative. If for every $x \in M$, $X \in \mathcal{D}$ and i 1,...,k the right hand side of (1.7) is zero,

then A = 0 for any $X \in \mathfrak{D}_{\mathbf{X}}$ and $Y \in \mathfrak{D}_{\mathbf{X}}^{\perp}$. If means that

A X = 0 for every $Y \in \mathfrak{D}^{\perp}$, $X \in \mathfrak{D}$ and $x \in M$. Since $\psi_{\mid \mathfrak{D}^{\perp}}$ is

an epimorphism onto \mathfrak{D} and $(A X, W) = (\alpha(X, W), \varphi Y)$ for any

W \in TM, \propto (X,W) \in \mathcal{AH} for any X \in \mathfrak{D} and W \in TM. By Proposition (0.1) ∇ f = 0 ,i.e. M'is a generic product. The proof is completed.

Suppose now that M is a mixed foliate proper CR - submanifold. Then (1.4) reduces to the following

(1.8)
$$2 \| \mathbf{A}^T \mathbf{X} \|^2 = -\mathbf{H}^1 (\mathbf{X}, \mathbf{Y})$$

for $X \in \mathfrak{D}$, and $Y \in \mathfrak{D}^1$.

For a mixed foliate submanifold the equation of Gauss implies (1.9) $H^{-1}(X,Y) = R(X,Y,X,Y) + R(JX,Y,JX,Y)$

for $X \in \mathfrak{D}$ and $Y \in \mathfrak{D}^{\perp}$.

In fact, if $X \in \mathfrak{D}$ and $Y \in \mathfrak{D}^{\perp}$, $\alpha(X,Y) = \alpha(J^{\perp}X,Y) = 0$. Hence $\int_{\mathbb{R}^{1}} \mathbb{R}^{1}(X,Y,X,Y) = \mathbb{R}(X,Y,X,Y) - (\alpha(X,X),\alpha(Y,Y))$ $(1.10) \begin{cases} \mathbb{R}^{1}(J^{\perp}X,Y,J^{\perp}X,Y) = \mathbb{R}(J^{\perp}X,Y,J^{\perp}X,Y) - (\alpha(J^{\perp}X,J^{\perp}X),\alpha(Y,Y)) \end{cases}$

The holomorphic distribution \Im is integrable, so $\alpha(J^1X,J^1X) = (J^{1^2}X,X) = -\alpha(X,X)$, (see, for instance [1]). Therefore (1.10) implies (1.9).

Consequently

(1.11)
$$2 \| A^T X \|^2 = -R(X,Y,X,Y) - R(J'X,Y,J'X,Y)$$

for $X \in \mathfrak{D}$ and $Y \in \mathfrak{D}^{\perp}$

If there are $x \in M$, $X \in \mathfrak{D}$ and $Y \in \mathfrak{D}^{\perp}$ such that the right hand

side of (1.11) is negative then we have a contradiction, hence M is holomorphic or purely real. If the right hand side is zero for any $x \in M$, $X \in \Omega$ and $Y \in \Omega^{\perp}$, then $A^{\top}X = 0$, i.e.

 A^{T} X = 0. In manner as in the previous case we conclude from $J^{\dagger}Y$

this that $\nabla f = 0$. Therefore we have proved

Theorem 1.4. Let M be a mixed foliate CR - submanifold of a Kählerian manifold. If the Riemannian sectional curvature of M is non-negative, then M is a generic product. If at a point of M the Riemannian sectional curvature of M is positive, then M is holomorphic or totally real.
